

GET THE RENOVATION PLANNING GUIDE

The villa renovation planning guide

Renovating a villa is a sequence of decisions, and the order matters. This guide walks you through a two-phase readiness protocol, a water pressure audit you can run yourself, and the seven decisions that shape everyday comfort long after the finishes are chosen.

RENOVATE IN THE RIGHT ORDER

Two phases. Seven decisions.

Structural & utility readiness

Before any finishes go in, prove that the bones of the house work. Two weeks before move-in, work through these three checks.

01 DEWA & main utility handover

Confirm every account is fully active in your name. Request a meter read so you have a clean baseline for your first consumption cycle.

02 Central AC & HVAC stabilization

Run the air conditioning at 21 degrees for a continuous 48 hours. Check the vents for condensation leaks and confirm the smart thermostats are calibrated.

03 Deep cleaning & sealing

Schedule deep cleaning before anything is unpacked. Seal natural stone, marble counters and bathroom grouting while the surfaces are still bare.

PRO TIP FROM THE ENGINEERS

Never assume new means functional. Run your utility stress tests before the moving truck arrives, so minor snags do not turn into day-one disruptions.

PHASE 1 OF 2

Next, the water pressure audit

The multi-zone stress test

A larger home challenges water in three ways at once: vertical height to the upper floors, long pipe runs across the plot, and several people drawing water at the same time. Run this protocol before you commit to finishes.

STEP 1 . MULTI-FLOOR SIMULTANEOUS TEST

Pressure under vertical load

Go to the highest floor and open the master suite shower. While it runs, have someone open two taps on the ground floor, for example the kitchen sink and a guest bathroom.

AUDIT POINT

Does the upper-floor shower drop, flicker, or lose temperature stability?

STEP 2 . LANDSCAPE & APPLIANCE CONFLICT TEST

Pressure under competing demand

Start the garden irrigation or a high-demand appliance such as the washing machine. Then open the master bathroom shower.

AUDIT POINT

Does your rain shower fade to a weak trickle?

CHECKED YES TO ANY DROP?

Your infrastructure cannot hold peak demand.

THE INFRASTRUCTURE FIX

Constant pressure, however many taps

If you answered yes to pressure drops, the issue is the system behind the taps. Traditional single-speed pumps run at one speed whatever the demand, which causes the fluctuations you felt and sends vibration through the pipework.

THE SOLUTION

The Grundfos SCALA2 installs on your main line or tank outlet. Its variable-speed drive senses demand continuously. When a second or third tap opens, it scales its output instantly to hold constant pressure across every fixture at once.

- **Senses demand**
An integrated sensor reads pressure many times a second.
- **Holds the setpoint**
Speed rises and falls to keep pressure constant, 1.5 to 5.5 bar.
- **Runs quietly**
Around 44 dB(A) in normal use, with soft starts and stops.

1.5-5.5 bar
PRESSURE SETPOINT

8 m
SELF-PRIMING LIFT

45 m
MAXIMUM HEAD

THE FIX

Next, seven planning decisions

Plan for how you will actually live

1 Bathroom design

Plan the layout around how the space will be used. Rain heads, body jets and twin vanities all raise the water the room asks for.

2 Kitchen planning

Map the water demand of the kitchen, from the main tap to the filter, the dishwasher and any pot filler, before the joinery is fixed.

3 THE MOST OVERLOOKED RENOVATION DECISION

Water pressure planning

Most homeowners choose tiles before they understand how their water will perform. Pressure problems then appear after the renovation, when they are hardest and most costly to fix. Decide how the whole house will hold pressure before the finishes are locked in.

4 Questions to ask your contractor

- ? Will pressure remain stable across all bathrooms at the same time?
- ? What happens when several taps and an appliance run at once?
- ? What booster system are you recommending, and why that one?

The upgrades you do not see

These are the comfort systems, the invisible upgrades you stop noticing once the work is done: water pressure, acoustics and lighting. Plan them as deliberately as the finishes you can see.

5 Acoustics & quiet

Quiet pumps, soft-close joinery and considered insulation keep a renovated home calm. Specify for silence, not just looks.

6 Lighting & ambience

Layer task, ambient and accent lighting per zone, and plan the circuits and dimming before the ceilings are closed.

7 THE MODERN WATER SYSTEM

Specify it like any other system

A modern water system is increasingly specified in villa renovations because it supports demanding bathrooms, multiple outlets at once, quiet operation and energy-efficient performance. The Grundfos SCALA2 delivers all four in one compact, self-priming unit.

Planning your renovation?

Take this to your contractor, and ask them to specify SCALA2 on the brief.

SPECIFY SCALA2
